Although this program has been tested by the contributor, no warranty, express or implied, is made by the contributor, Digital Equipment Computer Users Society or Digital Equipment Corporation as to the accuracy or functioning of the program or related program material, and no responsibility is assumed by these parties in connection therewith.

The expression of a function as a truncated Taylor series is a well known calculational technique. In fact, it is the principle method of solution of linear differential equations. The method can easily be extended to the solution of nonlinear differential equations, the solution of transcendental algebraic equations, and integrals.\* The program TAYEX can be used to yield approximation solutions to all of these.

The Taylor series of  $f(x)$  is written

$$f(x) = f(x)|_{x=x_0} + \sum_{n=1}^{\infty} \frac{1}{n!} \left. \frac{d^{(n)} f(x)}{dx^n} \right|_{x=x_0} (x-x_0)^n$$

Thus, if all of the derivatives of a function are known, the function is known. A truncation after  $N$  terms is a good approximation if  $x$  is not too far from  $x_0$ . Now consider the differential equation in the form

$$y'' = F(y', y, x)$$

Since it is second order there will be two constants in the solution which must be determined by initial conditions. For these we choose  $y(x)$  and  $y'(x)$  and  $y(x_0)$ . Now find the higher derivatives of  $y(x)$  by differentiating  $y''$ . Thus, we have the constants:

$$y(x_0) = C_1$$

$$y'(x_0) = C_2$$

$$y''(x_0) = F(y', y, x)|_{x=x_0} = F(C_2, C_1, x_0)$$

$$y'''(x_0) = \left. \frac{d}{dx} F(y', y, x) \right|_{x=x_0}$$

$$y''''(x_0) = \left. \frac{d^2}{dx^2} F(y', y, x) \right|_{x=x_0}$$

etc.

\*The method is mentioned in Rainville, "Elementary Differential Equations", Macmillan Third Edition, page 297.

and so on. The constants  $c_1$  and  $c_2$  are the boundary conditions. In taking the higher derivatives the lower derivatives will appear. Thus, the expression for  $y^{(iv)}$  may contain  $y''''$ ,  $y'''$  and  $y''$  as well as  $y$  and  $x_0$ . However, the iteration from lower derivatives to higher is well defined and straight forward.

Example Solve the harmonic oscillator problem

$$y'' + \frac{k}{m} y = 0$$

for  $y'(0) = 0$ ,  $y(0) = 1$

Solution

$$y(0) = 1$$

$$y'(0) = 0$$

$$y''(0) = -\frac{k}{m} y(0) = -\frac{k}{m}$$

$$y'''(0) = -\frac{k}{m} y'(0) = 0$$

$$y^{(iv)}(0) = -\frac{k}{m} y''(0) = \frac{k^2}{m^2}$$

$$y^{(v)}(0) = -\frac{k}{m} y'''(0) = 0$$

etc.

Thus, the solution is

$$y = 1 - \frac{\left(\frac{k}{m}\right)}{2!} t^2 + \frac{\left(\frac{k}{m}\right)^2}{4!} t^4 + \dots$$

$$= \cos \sqrt{\frac{k}{m}} t$$

Example: Solve the large displacement pendulum problem with boundary conditions:

$$A|_{t=0} = A_0$$

$$\frac{dA}{dt} \Big|_{t=0} = 0 \quad 2$$

Solution: The equation of motion for a pendulum of mass  $m$  and length  $r$  is:

$$mr \frac{d^2 A}{dt^2} = -mg \sin A$$

Then

$$A(0) = A_0$$

$$A'(0) = 0$$

$$A''(0) = -\frac{g}{r} \sin A_0$$

$$A'''(0) = -\frac{g}{r} \cos A_0 A'_0 = 0$$

$$\begin{aligned} A^{IV}(0) &= -\frac{g}{r} (-\sin A_0 A_0'^2 + \cos A_0 A_0'') \\ &= \frac{g^2}{r^2} \sin A_0 \cos A_0 \end{aligned}$$

The answer is

$$A(t) = A_0 - \frac{1}{2!} \frac{g}{r} \sin A_0 t^2 + \frac{1}{4!} \frac{g^2}{r^2} \sin A_0 \cos A_0 t^4 + \dots$$

which is for small displacements ( $\sin A_0 \approx A_0, \cos A_0 = 1$ )

$$A(t) = A_0 \cos \sqrt{\frac{g}{r}} t$$

Example: Solve the simultaneous equations:

$$\frac{d^2 x}{dt^2} = -k y$$

$$\frac{d^2 y}{dt^2} = -m x^2$$

with boundary conditions

$$x(0) = y(0) = 1$$

$$x'(0) = y'(0) = 0$$

Solution:

$$x(0) = 1$$

$$x'(0) = 0$$

$$x''(0) = -k y(0) = -k$$

$$x'''(0) = -k y'(0) = 0$$

$$x^{IV}(0) = -k y''(0) = -k(-m x^2(0)) = km$$

etc.

$$y(0) = 1$$

$$y'(0) = 0$$

$$y''(0) = -m x^2(0) = -m$$

$$y'''(0) = -m 2x(0)x'(0) = 0$$

$$\begin{aligned}y^{IV}(0) &= -2m(x'^2(0) + x(0)x''(0)) \\&= 2mk\end{aligned}$$

etc

One pass of TAYEX will have to be for  $x(t)$  and one for  $y(t)$ .

The main restriction to this method is due to the truncation error. In general, for values of the variable close to the point of expansion, the approximation will be good. However, the amount of error will depend on the problem to be solved. Thus it is up to the user to determine the valid range of the expansion. This can sometimes be done by comparing values obtained after  $n$  terms and after  $n-1$  terms.

The appended worked example shows the expansion of the function  $\cos x$  where  $x$  is in radians it is calculated for each 0.1 radian between  $x=0$  and  $x=3.2$ . Note that the error in the expansion at  $x=3.14$  is about 1%.

## Operating Instructions

### Loading

Load the floating point package and then TAYEX with the binary loader.

### Starting

1. Load program with binary loader.
2. Set 0200 in the switch register, press load address.
3. Press START. The program will respond by asking for the derivatives (TAYEX will divide by  $n!$ ) and initial X value and DX the incrementing constant. The program will then type "LD SR WITH NUM. OF PTS, HIT CONT", load the switch register with the number of points to be calculated (Be sure that this number is converted to OCTAL).
4. Restart at 0200.

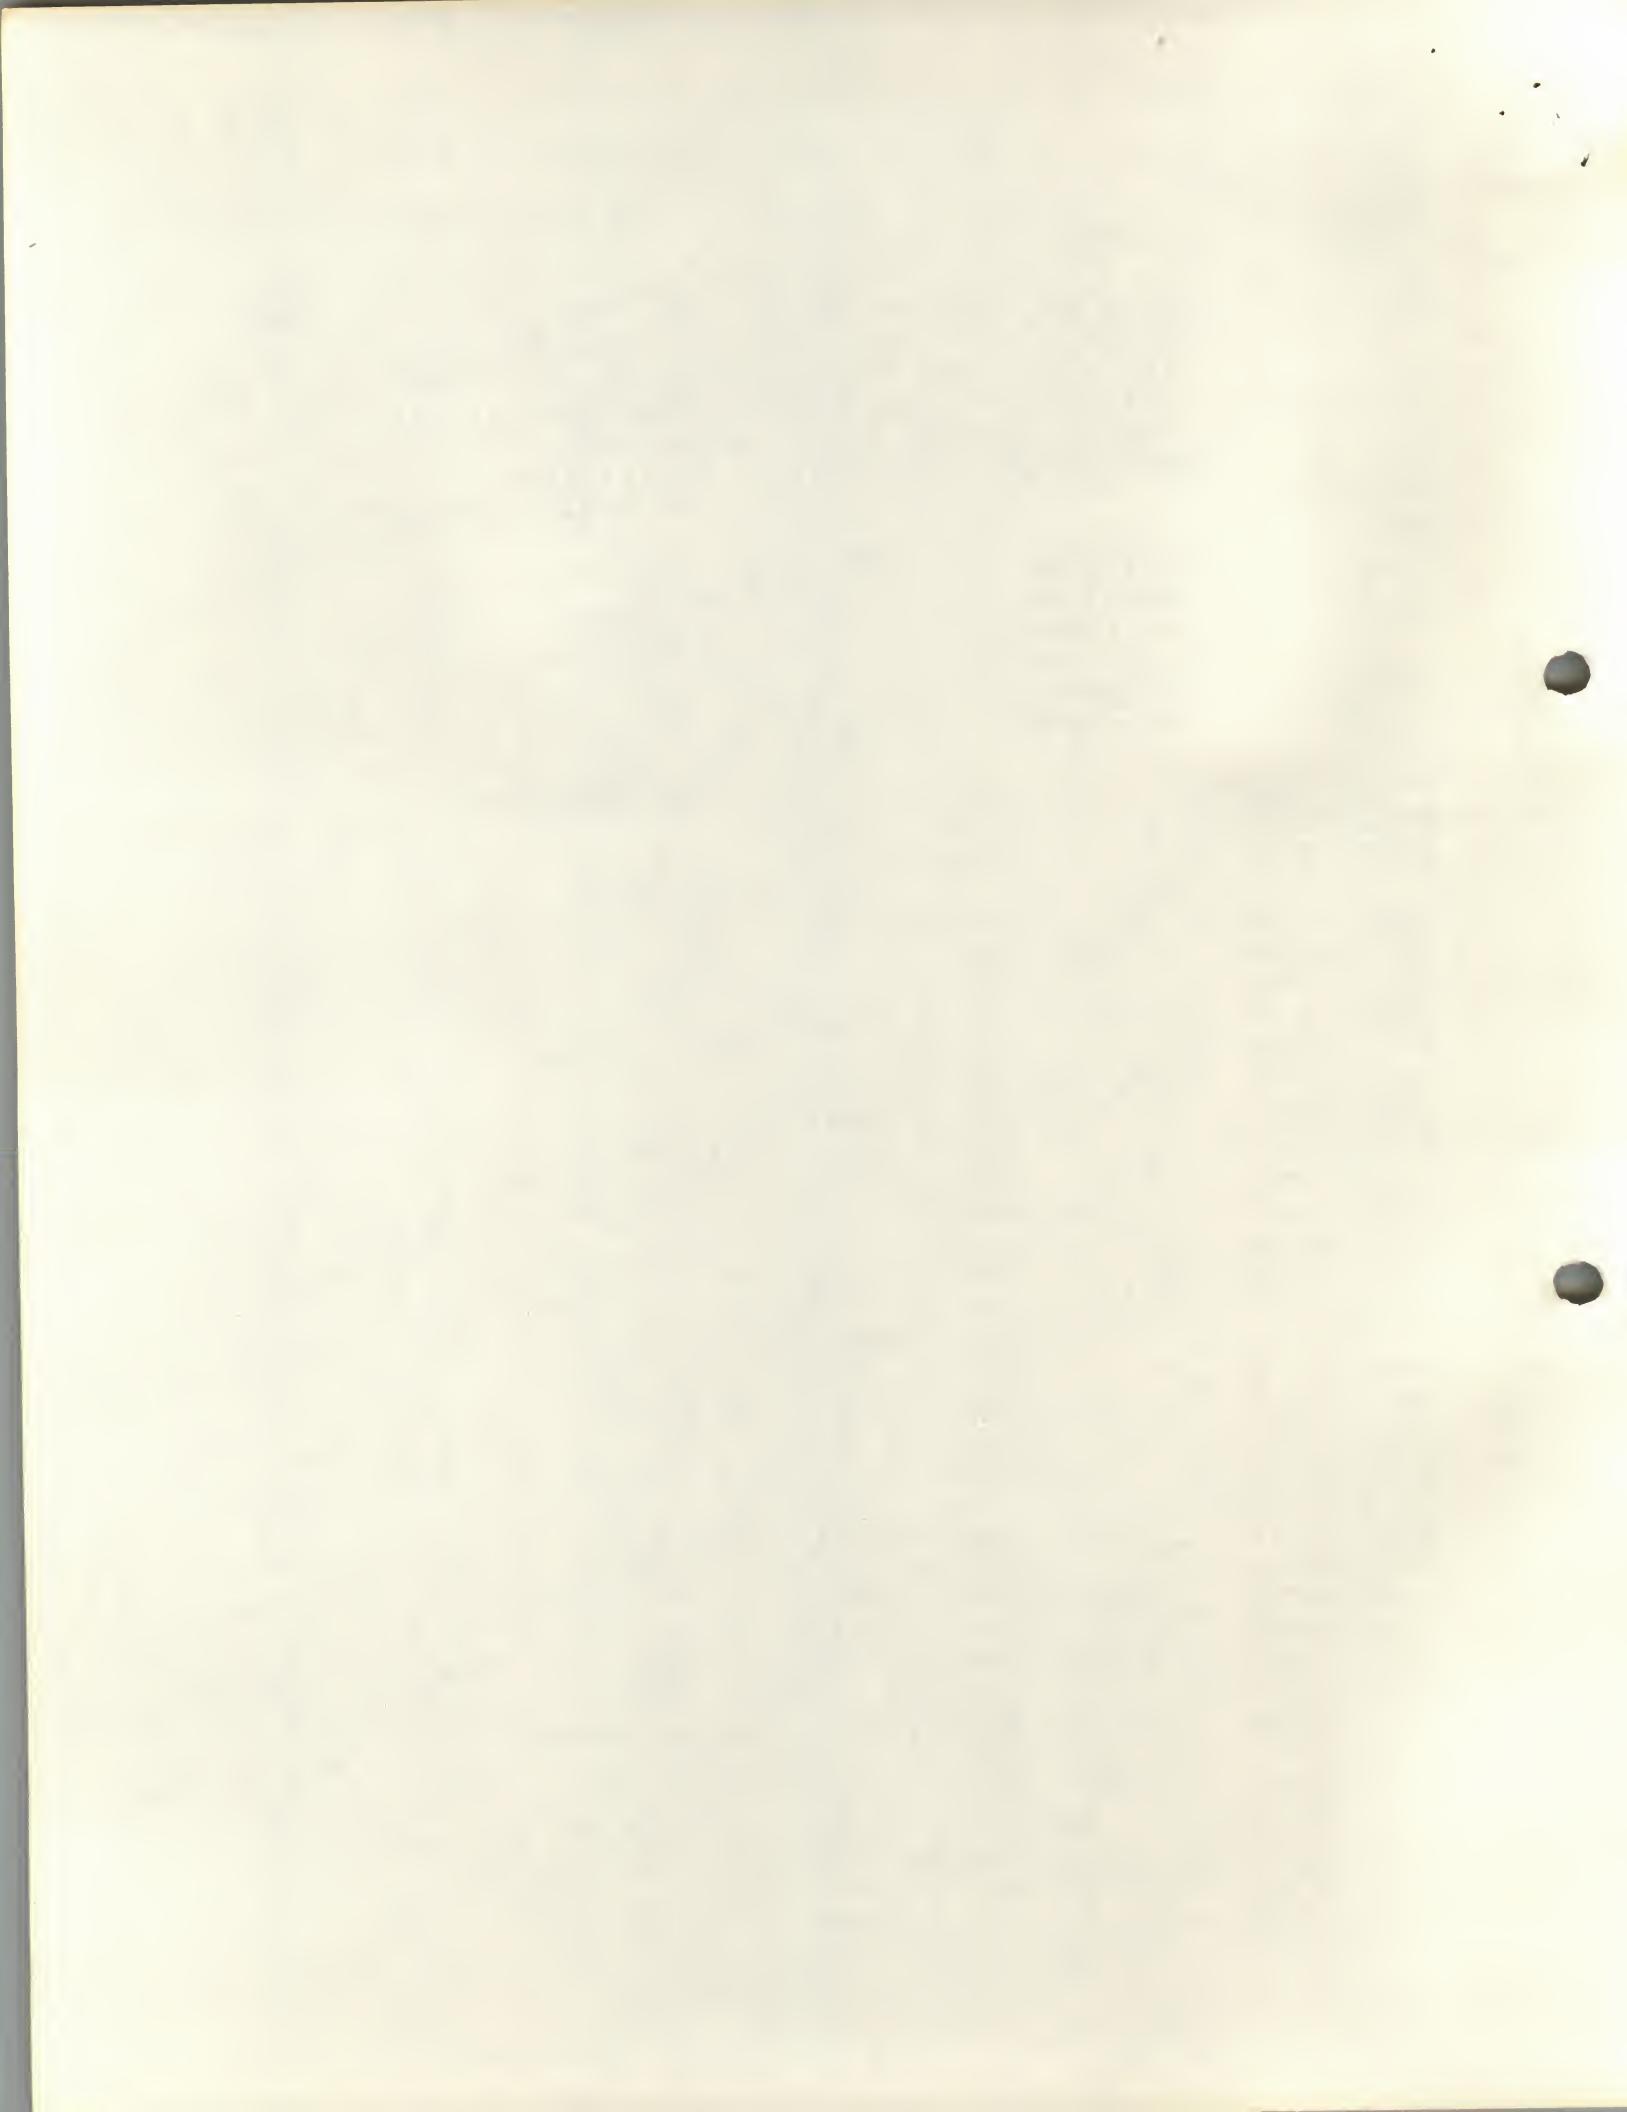

```

001      /TAYEX
